

# LMS SUMMER SCHOOL 2023—SOME TOPICS IN COMPUTATIONAL NUMBER THEORY PROBLEMS

LEWIS COMBES

## 1. LECTURE 1 - IRRATIONAL AND TRANSCENDENTAL NUMBERS

**Problem 1.1.** Let  $a, b \in \mathbb{Z}$ . Write down quadratic integer polynomials  $P_1(x)$ ,  $P_2(x)$  such that

$$P_1(\sqrt{a}) = 0, \quad P_2(\sqrt{b}) = 0.$$

By squaring  $\sqrt{a} + \sqrt{b}$  and rearranging, find a third integral polynomial  $P_3(x)$  such that

$$P_3(\sqrt{a} + \sqrt{b}) = 0.$$

What do you notice about the degrees of  $P_1$ ,  $P_2$  and  $P_3$ ? If you repeated the process for the algebraic numbers  $\sqrt{a}$ ,  $\sqrt[3]{b}$ , what would you expect the degree of  $P_3$  to be?

**Problem 1.2.** Recall the Lindemann-Weierstrass theorem: if  $\theta$  is an algebraic number, then  $e^\theta$  is transcendental. Use Lindemann-Weierstrass to prove the transcendence of

- (i)  $e^2$
- (ii)  $\log(2)$
- (iii)  $\cos(1)$  (hint: consider the polynomial  $x^2 - 2\cos(1)x + 1$  evaluated at  $e^i$ )

## 2. LECTURE 2 - THE RIEMANN HYPOTHESIS

**Problem 2.1.** Using the product expansion

$$\frac{\sin(x)}{x} = \prod_{n=1}^{\infty} \left(1 - \frac{x^2}{n^2\pi^2}\right)$$

evaluated at  $x$  and  $ix$ , prove (in the manner of Euler<sup>1</sup>) that

$$\zeta(4) = \frac{\pi^4}{90}.$$

---

<sup>1</sup>Which is to say, without worrying about technical details like convergence.

Using the same trick as above, with canny choices of  $cx$  for constants  $c \in \mathbb{C}$ , it is possible to write down all even values of the zeta function. What is  $\zeta(8)$ ?

**Problem 2.2.** In this question, we prove the Euler product expansion of the zeta function. Recall that

$$\zeta(s) := \sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_{p \text{ prime}} \left(1 - \frac{1}{p^s}\right)^{-1}.$$

First, compute

$$\left(1 - \frac{1}{2^s}\right) \zeta(s)$$

as a series in  $s^{th}$  powers of integers. What do you notice about these integers? Now compute

$$\left(1 - \frac{1}{3^s}\right) \left(1 - \frac{1}{2^s}\right) \zeta(s).$$

Again, what do you notice? How can one continue this process to prove the Euler product formula? Where does the product converge?

**Problem 2.3.** Recall the zeta functional equation:

$$\zeta(s) = 2^s \pi^{s-1} \sin\left(\frac{\pi s}{2}\right) \Gamma(1-s) \zeta(1-s).$$

Using this, and the fact that  $\Gamma(s) \neq 0$  for all  $s \in \mathbb{C}$ , prove the following: if  $\rho$  is a zero of  $\zeta$  in the critical strip (so  $0 < \operatorname{Re}(\rho) < 1$ ) but **not** on the critical line (so  $\operatorname{Re}(\rho) \neq \frac{1}{2}$ ), then  $\zeta$  has another zero  $\rho^*$ , which is the reflection of  $\rho$  in the critical line.

### 3. LECTURE 3 - DIRICHLET'S THEOREM ON PRIMES IN ARITHMETIC PROGRESSIONS

**Problem 3.1.** Let  $\chi : \mathbb{Z} \rightarrow \mathbb{C}$  be a **totally multiplicative function**. This means that

$$\chi(ab) = \chi(a)\chi(b)$$

for all  $a, b \in \mathbb{Z}$ . Define the  **$L$ -series of  $\chi$**  as

$$L(\chi, s) = \sum_{n=1}^{\infty} \frac{\chi(n)}{n^s}.$$

Assuming  $L(\chi, s)$  converges for  $\operatorname{Re}(s) > d$  for some  $d \in \mathbb{R}^+$ , prove that

$$L(\chi, s) = \prod_{p \text{ prime}} \left(1 - \frac{\chi(p)}{p^s}\right)^{-1}$$

for  $\operatorname{Re}(s) > d$ .

(Hint: write  $\frac{1}{1-\frac{1}{p^s}}$  as a geometric series, then use the unique factorisation of integers.)

**Problem 3.2.** Fix some integer  $m$ . Let  $G$  be the set of homomorphisms  $\mathbb{Z}/m\mathbb{Z} \rightarrow \mathbb{C}$ . Prove  $G$  is an abelian group under pointwise multiplication, i.e.

$$(f \cdot g)(a) := f(a)g(a).$$

What is the identity element of  $G$ ? Why is  $\cdot$  commutative? Why is it associative? What is the inverse of  $f \in G$ ?

This group  $G$  is the **group of Dirichlet characters mod  $m$** .

Show that the image of any  $f \in G$  lies on the unit circle in  $\mathbb{C}$ . Show that  $|G| = \phi(m)$ , where  $\phi$  is Euler's totient function, the number of elements of  $\mathbb{Z}/m\mathbb{Z}$  coprime to  $m$ .

Finally, prove the following:

**Lemma 3.3.** Let  $a \in (\mathbb{Z}/m\mathbb{Z})^\times$ . Then

$$\sum_{\chi} \chi(a) = \begin{cases} \phi(m) & \text{if } a = 1 \\ 0 & \text{else} \end{cases}$$

where the sum runs over all  $\chi$  in the character group mod  $m$ .

And hence, that

**Lemma 3.4.** Suppose  $a, n$  are coprime to  $m$ . Then

$$\sum_{\chi} \chi(a)^{-1} \chi(n) = \begin{cases} \phi(m) & \text{if } n \equiv a \pmod{m} \\ 0 & \text{else} \end{cases} \quad (3.1)$$

#### 4. LECTURE 4 - ELLIPTIC CURVES

**Problem 4.1.** Recall Diophantus' elliptic curve  $6Y - Y^2 = X^3 - X$ . Find a substitution  $x = aX + b$ ,  $Y = cX + d$  that puts it into *short Weierstrass form*, i.e. of the form

$$y^2 = x^3 + sx + t$$

for some  $s, t \in \mathbb{Q}$ .

**Problem 4.2.** This problem concerns the group law on an elliptic curve. Let  $E$  be the elliptic curve  $y^2 = x^3 - x + 9$ , and let  $P = (1, 3)$ . Show that  $P$  lies on  $E$ . Compute  $2P$  in the following way:

- (1) Compute the tangent line  $\ell$  to  $E$  at  $P$  by implicitly differentiating the equation for  $E$ .
- (2) Find the point  $R$  of  $E$  where  $\ell$  intersects  $E$  for a third time.
- (3) Find the point  $2P$  by reflecting  $R$  in the  $x$ -axis.

Writing the coordinates of  $2P$  as  $(x, y)$ , compute the point  $(x, y + 3)$ .
